

B.FED Global Market-Maker Program

C2C Fiat Market × USD-C Liquidity Market × HNY

Open-Order Book

Become a Liquidity Provider — Generate Value From Every Genuine Trade

As B.FED transitions into open-trading mode, two interconnected trading ecosystems will take shape across the platform:

the C2C fiat-trading zone and the HNY / USD-C open-order book. USD-C will serve as the core settlement asset for the upcoming open-order-book market.

This means market-makers have access to multiple revenue streams. During the C2C phase, market-makers can already earn trading returns via: HNY bid-ask spreads, as well as exchange-rate spreads between USD-C and various fiat currencies.

Once the open-order book goes live, market-makers will gain additional income from: HNY / USD-C bid-ask spreads plus commission rebates generated from real-world trading volume.

I. Understand How Market-Makers Earn Money in One Sentence

If you want to grasp the B.FED market-maker model in 10 seconds:

You deploy your own capital to place buy and sell orders on the order book. When users fill your orders, you profit from the bid-ask spread. Higher market activity translates into more executed trades for you. After the order-book launch, you also qualify for commission rebates based on actual trading volume.

Key takeaway: **Market-makers do not profit from waiting for market prices to rise.**

Market-makers profit from trading activity itself.

II. Four Core Revenue Streams for B.FED Market-Makers

Revenue Stream	Current C2C Phase	Future Open-Order-Book Phase
HNY Bid-Ask Spread	✓	✓
USD-C / Fiat Currency Spread	✓	—
HNY / USD-C Order-Book Spread	—	✓
Trading Commission Rebates	- / Limited	✓

Market-makers can therefore build trading returns from two asset classes: **HNY and USD-C.**

III. First Revenue Stream: Capturing HNY Bid-Ask Spreads

This is the most direct revenue opportunity available within the current C2C fiat-trading zone.

Assume HNY trades near \$2.00 per unit. A market-maker may post quotes based on prevailing market conditions:

- **Buy Order (Bid):** \$1.98 / HNY
- **Sell Order (Ask):** \$2.03 / HNY

When a user sells HNY to you, you acquire HNY at your bid price of \$1.98. When another user purchases HNY from you, you sell HNY at your ask price of \$2.03.

The spread calculation: $\$2.03 - \$1.98 = \text{\$0.05 per HNY}$. This amount represents your HNY bid-ask spread profit.

IV. The Critical Concept: Capital Turnover

Market-making is not purchasing 10,000 HNY and waiting for its price to appreciate.

The core market-making logic follows this cycle: **Buy → Sell → Re-Buy → Re-Sell** continuously supplying two-sided market liquidity.

Example of one full turnover cycle for 10,000 HNY: Average spread: \$0.05 Theoretical spread gain:
 $10,000 \times \$0.05 = \500 .

When this effective turnover repeats multiple times daily, your total spread profit rises alongside total trading volume.

V. Second Revenue Stream: USD-C Fiat Exchange-Rate

Spreads

This is a high-value yet frequently overlooked revenue channel for B.FED market-makers.

USD-C is B.FED's **USD-denominated settlement asset**, pegged at a 1:1 baseline against the U.S. dollar.

Even so, real-world trading prices between USD-C and local fiat currencies fluctuate based on regional supply-and-demand dynamics, foreign-exchange rates, and available liquidity.

Example for the CNY market: 1 USD-C $\approx$ \$7.20.

A market-maker might publish these quotes:

- **Buy (Bid):** \$7.16 / USD-C
- **Sell (Ask):** \$7.24 / USD-C

When users sell USD-C, the market-maker takes the other side of the trade. When users demand USD-C, the market-maker provides liquidity by selling USD-C.

This creates a trading spread of **\$0.08 per USD-C unit**.

VI. Why USD-C Creates Viable Market-Making

Opportunities

Fiat prices for USD-C vary across countries and regions. Examples include:

- USD-C / CNY
- USD-C / JPY

- USD-C / KRW
- USD-C / HKD

Additional fiat pairs will roll out gradually as B.FED expands supported regional markets.

Market-makers with access to local fiat liquidity can provide two-sided quotes for their home markets:

- Japan-based market-makers: JPY ↔ USD-C
- China-based market-makers: CNY ↔ USD-C
- Korea-based market-makers: KRW ↔ USD-C

This structure naturally builds a network of localized global liquidity for B.FED.

VII. Dual Market-Making Capacity via HNY + USD-C

Market-makers can operate two independent profit-driven lines of business simultaneously:

1. **HNY Spread Business:** Earn profits from HNY bid-ask spreads.
2. **USD-C / Fiat Spread Business:** Earn profits from exchange-rate spreads between USD-C and local fiat currencies.

Accordingly, market-maker profitability is no longer exclusively tied to HNY price appreciation. Even during periods of stable HNY pricing, consistent genuine trading activity generates returns through **trading spreads and capital turnover**.

VIII. Third Revenue Stream: HNY / USD-C Spreads on the Open-Order Book

Once B.FED launches its open-order-book platform, USD-C will function as the primary settlement asset. The exchange will host the HNY / USD-C trading pair.

Buy Orders (Bid Side)

Bid Price	Quantity
-----------	----------

0.296 USD-C	5,000 HNY
0.295 USD-C	10,000 HNY
0.294 USD-C	20,000 HNY

Sell Orders (Ask Side)

Ask Price	Quantity
0.298 USD-C	5,000 HNY
0.299 USD-C	10,000 HNY
0.300 USD-C	20,000 HNY

Market-makers sustain two-sided order depth by maintaining active bid and ask orders to supply market liquidity.

IX. Core Profit Driver for Order-Book Market-Makers

The fundamental formula holds:

$$\text{Ask Price} - \text{Bid Price} = \text{Bid-Ask Spread}$$

Example: Bid price: 0.296 USD-C Ask price: 0.299 USD-C Spread: 0.003 USD-C per HNY.

With executed volume totaling 10,000 HNY: Theoretical spread profit = $10,000 \times 0.003 = 30$ USD-C.

X. Per-Trade Profit Is Not the Primary Metric

The B.FED market-maker program is built around **high frequency × large volume × consistent trade execution**.

Sample scenario for one market-maker: Average executed order size: 500 HNY Average effective spread: 0.003 USD-C Theoretical profit per fill: 1.50 USD-C.

With 200 filled orders per day: $200 \times 1.50 = 300$ USD-C in theoretical daily spread returns.

As market scale grows, assume average order size rises to 1,000 HNY at 200 fills daily: Daily total traded volume = $200 \times 1,000 = \mathbf{200,000 \text{ HNY}}$.

Market-makers do not target windfall single-trade gains. Their objective is to ensure their liquidity gets continuously utilized by market participants.

XI. Fourth Revenue Stream: Trading Commission Rebates

Commission rebates will become a major income source once the open-order-book matures.

Workflow for every completed genuine trade:

1. Buyer fills an order
2. Seller fills an order
3. The system generates trading commissions
4. Per B.FED market-maker program rules, a portion of commissions flows into the market-maker incentive pool.

Market-makers earn commission entitlements determined by these factors:

- Market-maker tier
- Effective trading volume
- Number of valid executed trades
- Two-sided liquidity provision
- Continuous market-making uptime
- Order-book quality
- Overall market contribution

XII. Why Executed Trade Count Matters

Market vitality stems from actual trades.

It does not come from new user registrations, static account balances, or passive open orders alone. Real-world user actions — buying, selling, converting, and utilizing assets — drive healthy markets.

For this reason, the B.FED market-maker framework rewards not just large-capital participants. It also prioritizes participants who deliver consistent genuine trade execution.

XIII. Market-Maker Commission Rebate Model

A dual-metric evaluation framework is recommended: **Valid executed trade count + effective trading volume**

Market-Maker Tier	Target Daily Valid Executions	Commission Entitlement
MM1	20+ trades	Base Tier
MM2	50+ trades	Enhanced Tier
MM3	100+ trades	High Tier
MM4	150+ trades	Advanced Tier
Diamond	200+ trades	Top Tier

These figures are performance benchmarks, not mandatory requirements. Greater trading activity and more stable liquidity provision unlock higher commission entitlements.

XIV. What Does 200 Daily Executed Trades Represent?

Take a high-performing market-maker completing 200 valid fills each day: Over 30 calendar days:
 $200 \times 30 = \mathbf{6,000 \text{ monthly trades.}}$

If 100 active market-makers each average 200 fills per day: Total daily trades across the network =
 $100 \times 200 = \mathbf{20,000 \text{ trades per day.}}$ Monthly aggregate trades reach **600,000**.

This volume creates vastly improved market liquidity conditions.

The market-maker program's objective is not concentrating profits among a small group of participants; its goal is growing overall trading volume through broad-based participation.

XV. Three Dimensions of Market-Maker Returns

Total market-maker performance spans three dimensions:

1. Spreads

- HNY bid-ask spreads
- USD-C / fiat currency spreads
- HNY / USD-C order-book spreads

2. Trading Volume More fills drive more frequent capital turnover.

3. Commissions Higher total trade activity generates greater total commission pools, increasing commission allocations for participating market-makers.

This yields a composite profit formula:

Spread Profit × Turnover Rate + Commission Rebates = Total Market-Maker Returns

Successful market-making is defined by a combination of capital capacity, active participation, substantial market contribution, and reliable service quality.

XVI. What Assets Can a Market-Maker Support?

Mature market-makers will be able to operate multiple liquidity markets concurrently:

1. HNY / CNY — capture HNY-fiat spreads
2. HNY / JPY — capture HNY-JPY spreads
3. HNY / KRW — capture HNY-KRW spreads
4. USD-C / CNY — capture USD-C-CNY trading spreads
5. USD-C / JPY — capture USD-C-JPY trading spreads
6. USD-C / KRW — capture USD-C-KRW trading spreads
7. HNY / USD-C — earn order-book spreads via two-sided quoting after open-book launch

One market-maker can therefore service multiple independent liquidity markets.

XVII. Why USD-C Acts as the Core System Connector

C2C trading phase workflow:

Fiat Currency → USD-C

USD-C → HNY

Open-order-book phase workflow:

USD-C ↔ HNY

USD-C functions as the critical settlement bridge linking local fiat-currency markets to the global HNY open-trading market.

Simplified breakdown:

- Fiat currencies enable local-currency onboarding into the ecosystem.
- USD-C delivers a unified settlement unit across geographically separate markets.
- HNY is the instrument for global open-market trading.

XVIII. What B.FED Market-Makers Actually Operate

Market-makers are not primarily trading HNY or USD-C. Their core business is **liquidity provision**.

- HNY: tradable asset / commodity
- USD-C: core settlement asset
- Fiat currencies: local funding on-ramps

Market-makers deliver the guarantee that buyers can execute purchases on demand and sellers can complete sales on demand. Market-maker value rises proportionally with trading activity.

XIX. The Value of Early Market-Maker Onboarding

Liquidity, not asset supply, is the scarcest resource in emerging markets.

As overall trading volume expands, early market-makers accumulate long-term competitive advantages through:

- Historical execution track record
- Market-maker tier status
- Proven trading volume
- Community trust
- Market depth contribution
- Multi-market quoting capabilities

XX. B.FED Market-Making Is Not a Fixed-Return Program

B.FED offers no guaranteed returns for market-makers. There are no guaranteed daily yields, guaranteed monthly yields, principal-protected returns, or profit guarantees of any kind.

All market-making income originates from real-world market trades. Actual realized results are affected by:

- Overall market trading volume
- Bid-ask spread conditions
- Order fill rates
- Market price volatility
- Deployed liquidity size
- Inventory management practices
- Trading commission levels
- Competitive market dynamics
- Risk-management compliance rules

Market-making is a commercial market-driven business activity, not a fixed-income investment product.

XXI. Simplified Market-Maker Profit Formula

During C2C Phase

- HNY spread income

- USD-C / fiat exchange-rate spread income

After Open-Order-Book Launch

- HNY / USD-C order-book spread income
- Trading commission rebates

Total Market-Maker Income = (Spread Income × Executed Volume) + Commission Rebates

XXII. B.FED's Goal: Building a Global Market-Maker

Network

The platform's objective is not cultivating a small set of large individual traders. It aims to build out a **global network of market-makers**.

Moving forward, dedicated market-makers will operate across the globe: United States, Japan, South Korea, Greater China, Southeast Asia, Europe.

Within each geographic market, participants supply:

1. Local fiat-currency liquidity
2. HNY / USD-C trading liquidity

The end state: a **Global Liquidity Network**.

Market-makers across all regions jointly supply liquidity. Community participants around the world conduct trades. Trading activity generates commissions. Commissions feed back into the market-maker incentive system. Incentives enable further liquidity expansion.

This creates a self-sustaining global trading-liquidity cycle.

B.FED Global Market-Maker

You do not merely wait for markets — you build them.

Supply liquidity, facilitate executions, capture spreads, and share in the value generated by trading activity. This is not passively chasing opportunities; this is co-building a global marketplace.
